

Many projects. The right identity for each one.

Git Identity Manager helps developers manage personal, work and client GitHub accounts from VS Code.

Problem → solution → setup → daily use → what comes next

One developer. Several accounts to remember.

Wrong commit email

A client commit inherits a personal identity from global Git settings.

Unexpected sign-in

Moving to another repository triggers a credential prompt or access error.

Unclear permissions

A failed push leaves you guessing whether the account, token or repository policy is responsible.

Assign the account once. Apply it to the project.

Save your profiles, map each repository to its intended account, and apply the local Git identity and authentication setup.

Example

Personal portfolio → personal account

Client application → client account

Company platform → work account

Commit author and push authentication are different. The extension helps you configure both.

Start with the VS Code extension.

01

Download v1.6.2

Get the VSIX from the product website's Releases section.

02

Install from VSIX

VS Code → Extensions → ... → Install from VSIX. Select the file and reload.

03

Open your project

Use a local GitHub repository. Windows HTTPS setup requires Git Credential Manager.

04

Open the dashboard

Ctrl + Shift + P → GitHub: Open Control Panel Dashboard.

Requires VS Code 1.75+. The optional desktop companion runs from source and needs VS Code open.

Add. Assign. Apply. Check.

- **Add** a profile with browser login or a personal access token.
- **Assign** your project folder to the intended account.
- **Apply** the profile using Use for This Project.
- **Check** Health for the saved account and repository.

Repeat for your other account in a separate project window. Your existing commit and push tools stay part of the workflow.

Know what to do when access changes.

New project

Create a mapping and apply the chosen profile before working.

Expired login

Use Reauthenticate for a browser profile, or Save / Update Token.
Reapply the profile and check Health.

Push rejected

Check the account, token and project mapping. Branch protection, SSO and workflow permissions can still prevent a push.

You choose which project AI tools may read.

- Find the **AI Agent Access** card at the top of the dashboard.
- Review the project and account; select **Enable AI Access** and confirm.
- Connect a local MCP client to read repository metadata.
- Select **Disable AI Access** to withdraw approval.

Read only means read only.

This connector does not commit, push or edit. Your token stays inside VS Code. Enabling approval alone does not configure an AI client.

Small releases. Concrete improvements.

1.1–1.3

Saved authentication, repository credential isolation, desktop companion and useful account health diagnostics.

1.4–1.5

In-place reauthentication, clearer browser account selection and safe username repair.

1.6–1.6.2

Read-only AI repository tools, explicit approvals and visible dashboard access controls.

Every version's download and detailed changes are available on the website.

A clear line between available and planned.

Available now

Windows-first extension, local identity, saved accounts, health checks, shared desktop view and approved AI repository metadata.

Local Windows automated checks and one approved live-project read/push have succeeded. Full two-account verification remains open.

Next

Live account isolation and platform vault verification; pull-request reads; GitHub Actions visibility and controls; tested Windows/macOS/Linux installers.

No release dates promised. Enterprise Server, GitLab and Bitbucket are later ideas, not current features.

Try two projects. Keep the results simple.

- Assign project A to account A and project B to account B.
- Check Health, then use harmless test branches for your normal Git workflow.
- Enable AI reads in A. Confirm B remains denied until separately approved.
- Disable A. Confirm further AI reads fail while B keeps its own access.

Share pass/fail results and useful errors, never tokens or connection keys.
